Specific Question:
In adults with ankle OA is hyaluronic acid injection better than no treatment or conservative treatment, for pain, function, and patient satisfaction?

Clinical bottom line
A Cochrane Systematic review suggests that hyaluronic acid is not better than no treatment or conservative treatment for ankle OA. The review suggests that there is uncertainty over the benefit of hyaluronic acid for the treatment of ankle osteoarthritis compared to placebo. Hyaluronic acid injections might be conditionally recommended when simple analgesics have failed.

There is insufficient data to create a synthesis of the evidence as a base for future guidelines on the use of hyaluronic acid injections as part of the management for ankle OA. Further Research is required to ascertain its benefits and risks.

Why is this important?
The management of ankle OA continues to be a challenge for clinicians. Previous CAT questions have identified poor evidence regarding conservative ankle OA management versus no treatment and surgical solutions. Hyaluronic acid injection is a treatment intervention currently available on the NHS in some areas. It is important to establish best clinical practice and therefore assess the current available evidence on hyaluronic injections to assist healthcare commissioners as well as practitioners in the allocation and clinical reasoning of treatment.

Summary

It is unclear if there is a benefit or harm for hyaluronic acid injections as a treatment for ankle OA compared to placebo at six months based on low quality of evidence. Inconclusive results were found comparing hyaluronic acid injections to other conservative treatments (Witteveen et al. 2015).

Overall, the current level of evidence shows serious limitations and currently there is insufficient data to create a synthesis of the evidence as a base for future guidelines on the use of hyaluronic injections for ankle OA (Witteveen et al. 2015).

Implications for Practice/research

Further, larger, more robust studies are required to identify if hyaluronic injections are statistically more effective in addressing levels of pain and function when compared to placebo or other conservative measures for the management of adult ankle OA

Hyaluronic acid injections might be conditionally recommended when simple analgesics have failed (Witteveen et al. 2015).

What would you tweet? (140 characters)

Promising results for the use hyaluronic injections in symptomatic ankle OA but need better-quality studies to establish efficacy.
